#### Introduction 1

This is a very first draft of our article. The current \*tentative\* title is "A guided tour in targeted learning territory".

Explain our objectives and how we will meet them. Explain that the symbol Findicates more delicate material.

Use sectioning a lot to ease cross-referencing.

Do we include exercises? I propose we do, and to flag the corresponding subsections with symbol  $\square$ .

```
set.seed(54321) ## because reproducibility matters...
suppressMessages(library(R.utils)) ## make sure it is installed
suppressMessages(library(tidyverse)) ## make sure it is installed
suppressMessages(library(ggplot2)) ## make sure it is installed
suppressMessages(library(caret)) ## make sure it is installed
expit <- plogis
logit <- qlogis</pre>
```

Function expit implements the link function expit :  $\mathbb{R} \to ]0,1[$  given by  $\exp it(x) \equiv (1+e^{-x})^{-1}$ . Function logit implements its inverse function logit :  $]0,1[\to\mathbb{R}$  given by  $logit(p) \equiv log[p/(1-p)]$ .

# 2 A simulation study

blabla

**2.1** Reproducible experiment as a law. We are interested in a reproducible experiment. The generic summary of how one realization of the experiment unfolds, our observation, is called O. We view O as a random variable drawn from what we call the law  $P_0$  of the experiment. The law  $P_0$  is viewed as an element of what we call the model. Denoted by  $\mathcal{M}$ , the model is the collection of all laws from which O can be drawn and that meet some constraints. The constraints translate the knowledge we have about the experiment. The more we know about the experiment, the smaller is  $\mathcal{M}$ . In all our examples, model  $\mathcal{M}$  will put very few restrictions on the candidate laws.

Consider the following chunk of code:

```
draw_from_experiment <- function(n, full = FALSE) {</pre>
  ## preliminary
  n <- Arguments$getInteger(n, c(1, Inf))</pre>
  full <- Arguments$getLogical(full)</pre>
  ## ## 'Gbar' and 'Qbar' factors
  Gbar <- function(W) {</pre>
    expit(-0.2 + 3 * sqrt(W) - 1.5 * W)
  Qbar <- function(AW) {
    A \leftarrow AW[, 1]
    W \leftarrow AW[, 2]
    ## A * cos((1 + W) * pi / 5) + (1 - A) * sin((1 + W^2) * pi / 4)
    A * (\cos((1 + W) * pi / 5) + (1/3 \le W \& W \le 1/2) / 10) +
      (1 - A) * (\sin(4 * W^2 * pi) / 4 + 1/2)
  ## sampling
  ## ## context
  W <- runif(n)
  ## ## counterfactual rewards
  zeroW <- cbind(A = 0, W)
  oneW <- cbind(A = 1, W)
  Qbar.zeroW <- Qbar(zeroW)
  Qbar.oneW <- Qbar(oneW)
  Yzero <- rbeta(n, shape1 = 2, shape2 = 2 * (1 - Qbar.zeroW) / Qbar.zeroW)
  Yone <- rbeta(n, shape1 = 3, shape2 = 3 * (1 - Qbar.oneW) / Qbar.oneW)
  ## ## action undertaken
  A <- rbinom(n, size = 1, prob = Gbar(W))
  ## ## actual reward
  Y \leftarrow A * Yone + (1 - A) * Yzero
  ## ## observation
  if (full) {
    obs <- cbind(W = W, Yzero = Yzero, Yone = Yone, A = A, Y = Y)
  } else {
    obs <- cbind(W = W, A = A, Y = Y)
```

```
attr(obs, "Gbar") <- Gbar
attr(obs, "Qbar") <- Qbar
attr(obs, "QW") <- dunif
##
return(obs)
}
</pre>
```

We can interpret  $draw_from_experiment$  as a law  $P_0$  since we can use the function to sample observations from a common law. It is even a little more than that, because we can tweak the experiment, by setting its full argument to TRUE, in order to get what appear as intermediary (counterfactual) variables in the regular experiment. The next chunk of code runs the (regular) experiment five times independently and outputs the resulting observations:

```
(five_obs <- draw_from_experiment(5))</pre>
```

```
##

## <bytecode: 0xb301cb0>
## <environment: namespace:stats>
```

We can view the attributes of object five\_obs because, in this section, we act as oracles, *i.e.*, we know completely the nature of the experiment. From a probabilistic point of view, the attributes Gbar, Qbar and QW are infinite-dimensional features of  $P_0$ . There is more to  $P_0$  than  $\bar{G}_0$  (Gbar),  $\bar{Q}_0$  (Qbar), formally defined by

$$\bar{G}_0(W) \equiv P_0(A=1|W), \quad \bar{Q}_0(A,W) \equiv E_{P_0}(Y|A,W),$$
 (1)

and the marginal law  $Q_{0,W}$  of W under  $P_0$  (QW) — for instance the conditional law (not expectation) of Y given (A, W), but  $\bar{G}_0$ ,  $\bar{Q}_0$  and  $Q_{0,W}$  will play a prominent role in our story.

2.2 The parameter of interest, first pass. It happens that we especially care for a finite-dimensional feature of  $P_0$  that we denote by  $\psi_0$ . Its definition involves two of the aforementioned infinite-dimensional features:

$$\psi_0 \equiv E_{P_0} \left( \bar{Q}_0(1, W) - \bar{Q}_0(0, W) \right) 
= \int \left( \bar{Q}_0(1, w) - \bar{Q}_0(0, w) \right) dQ_{0, W}(w).$$
(2)

Acting as oracles, we can compute explicitly the numerical value of  $\psi_0$ .

Our interest in  $\psi_0$  is of causal nature. Taking a closer look at drawFromExperiment reveals indeed that the random making of an observation O drawn from  $P_0$  can be summarized by the following causal graph and nonparametric system of structural equations:

### ## plot the causal diagram

and, for some deterministic functions  $f_w$ ,  $f_a$ ,  $f_y$  and independent sources of randomness  $U_w$ ,  $U_a$ ,  $U_y$ ,

- 1. sample the context where the rest of the experiment will take place,  $W = f_w(U_w)$ ;
- 2. sample the two counterfactual rewards of the two actions that can be undertaken,  $Y_0 = f_y(0, W, U_y)$  and  $Y_1 = f_y(1, W, U_y)$ ;
- 3. sample which action is carried out in the given context,  $A = f_a(W, U_a)$ ;
- 4. define the corresponding reward,  $Y = AY_1 + (1 A)Y_0$ ;
- 5. summarize the course of the experiment with the observation O = (W, A, Y), thus concealing  $Y_0$  and  $Y_1$ .

The above description of the experiment draw\_from\_experiment is useful to ram home what it means to run the "full" experiment by setting argument full to TRUE in a call to draw\_from\_experiment. Doing so triggers a modification of the nature of the experiment, enforcing that the counterfactual rewards  $Y_0$  and  $Y_1$  be part of the summary of the experiment eventually. In light of the above enumeration,  $\mathbb{O} \equiv (W, Y_0, Y_1, A, Y)$  is output, as opposed to its summary measure O. This defines another experiment and its law, that we denote  $\mathbb{P}_0$ .

It is well known (do we give the proof or refer to other articles?) that

$$\psi_0 = E_{\mathbb{P}_0} (Y_1 - Y_0).$$

Thus,  $\psi_0$  compares (additively) the averages of the two counterfactual rewards. In other words,  $\psi_0$  quantifies the difference in average of the reward one would get in a world where one would always enforce action a=1 with the reward one would get in a world where one would always enforce action a=0. This said, it is worth emphasizing that  $\psi_0$  is a well defined parameter beyond its causal interpretation.

To conclude this subsection, we draw advantage from the possibility to sample full observations from draw\_from\_experiment by setting its argument full to TRUE in order to numerically approximate  $\psi_0$ . By the law of large numbers, the following chunk of code approximates  $\psi_0$  and shows it approximate value:

```
B <- 1e6 ## Antoine: 1e6 eventually
full_obs <- draw_from_experiment(B, full = TRUE)
(psi_hat <- mean(full_obs[, "Yone"] - full_obs[, "Yzero"]))</pre>
```

## [1] 0.06062293

In fact, the central limit theorem and Slutsky's lemma allow us to build a confidence interval with asymptotic level 95% for  $\psi_0$ :

```
sd_hat <- sd(full_obs[, "Yone"] - full_obs[, "Yzero"])
alpha <- 0.05
(psi_CI <- psi_hat + c(-1, 1) * qnorm(1 - alpha / 2) * sd_hat / sqrt(B))</pre>
```

## [1] 0.05997656 0.06126929

**2.3** The parameter of interest, second pass. Suppose we know beforehand that O drawn from  $P_0$  takes its values in  $\mathcal{O} \equiv [0,1] \times \{0,1\} \times [0,1]$  and that  $\bar{G}(W) = P_0(A=1|W)$  is bounded away from zero and one  $Q_{0,W}$ -almost surely (this is the case indeed). Then we can define model  $\mathcal{M}$  as the set of all laws P on  $\mathcal{O}$  such that  $\bar{G}(W) \equiv P(A=1|W)$  is bounded away from zero and one  $Q_W$ -almost surely, where  $Q_W$  is the marginal law of W under P.

Let us also define generically  $\bar{Q}$  as

$$\bar{Q}(A,W) \equiv E_P(Y|A,W).$$

Central to our approach is viewing  $\psi_0$  as the value at  $P_0$  of the statistical mapping  $\Psi$  from  $\mathcal{M}$  to [0,1] characterized by

$$\begin{split} \Psi(P) &\equiv E_P \left( \bar{Q}(1,W) - \bar{Q}(0,W) \right) \\ &= \int \left( \bar{Q}(1,w) - \bar{Q}(0,w) \right) dQ_W(w), \end{split}$$

a clear extension of (2). For instance, although the law  $\Pi_0 \in \mathcal{M}$  encoded by default (i.e., with h=0) in drawFromAnotherExperiment defined below differs starkly from  $P_0$ ,

```
draw_from_another_experiment <- function(n, h = 0) {
    ## preliminary
    n <- Arguments$getInteger(n, c(1, Inf))
    h <- Arguments$getNumeric(h)
    ## ## 'Gbar' and 'Qbar' factors
    Gbar <- function(W) {
        sin((1 + W) * pi / 6)
    }
    Qbar <- function(AW, hh = h) {
        A <- AW[, 1]
        W <- AW[, 2]</pre>
```

```
expit( logit( A * W + (1 - A) * W^2) +
           hh * 10 * sqrt(W) * A )
  }
  ## sampling
  ## ## context
  W \leftarrow runif(n, min = 1/10, max = 9/10)
  ## ## action undertaken
  A <- rbinom(n, size = 1, prob = Gbar(W))
  ## ## reward
  shape1 <- 4
  QAW <- Qbar(cbind(A, W))
  Y <- rbeta(n, shape1 = shape1, shape2 = shape1 * (1 - QAW) / QAW)
  ## ## observation
  obs \leftarrow cbind(W = W, A = A, Y = Y)
  attr(obs, "Gbar") <- Gbar</pre>
  attr(obs, "Qbar") <- Qbar</pre>
  attr(obs, "QW") <- function(x){dunif(x, min = 1/10, max = 9/10)}
  attr(obs, "shape1") <- shape1</pre>
  ##
  return(obs)
}
```

parameter  $\Psi(\Pi_0)$  is well defined, and numerically approximated by psi.Pi.zero in the following chunk of code:

```
five_obs_from_another_experiment <- draw_from_another_experiment(5)
integrand <- function(w) {
   Qbar <- attr(five_obs_from_another_experiment, "Qbar")
   QW <- attr(five_obs_from_another_experiment, "QW")
   ( Qbar(cbind(1, w)) - Qbar(cbind(0, w)) ) * QW(w)
}
(psi_Pi_zero <- integrate(integrand, lower = 0, upper = 1)$val)</pre>
## [1] 0.1966687
```

(easy algebra reveals that  $\Psi(\Pi_0) = 59/300$  indeed).

**2.4** Being smooth, first pass. Luckily, the statistical mapping  $\Psi$  is well behaved, or smooth. Here, this colloquial expression refers to the fact that, for each  $P \in \mathcal{M}$ , if  $P_h \to_h P$  in  $\mathcal{M}$  from a direction s when the real parameter  $h \to 0$ , then not only  $\Psi(P_h) \to_h \Psi(P)$  (continuity), but also  $h^{-1}[\Psi(P_h) - \Psi(P)] \to_h c$ , where the real number c depends on P and s (differentiability).

For instance, let  $\Pi_h \in \mathcal{M}$  be the law encoded in draw\_from\_another\_experiment with h ranging over [-1,1]. We will argue shortly that  $\Pi_h \to_h \Pi_0$  in  $\mathcal{M}$  from a direction s when  $h \to 0$ . The following chunk of code evaluates and represents  $\Psi(\Pi_h)$  for h ranging in a discrete approximation of [-1,1]:

```
approx <- seq(-1, 1, length.out = 1e2)
psi_Pi_h <- sapply(approx, function(t) {
  obs_from_another_experiment <- draw_from_another_experiment(1, h = t)
  integrand <- function(w) {
    Qbar <- attr(obs_from_another_experiment, "Qbar")
    QW <- attr(obs_from_another_experiment, "QW")
    (Qbar(cbind(1, w)) - Qbar(cbind(0, w)) ) * QW(w)</pre>
```

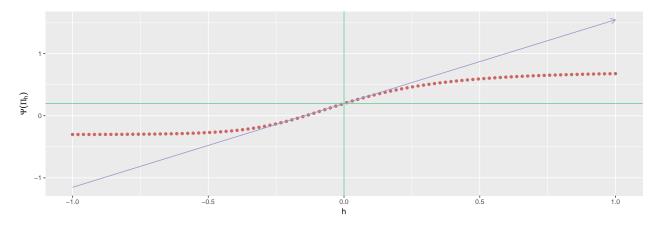

Figure 1: Evolution of statistical parameter  $\Psi$  along fluctuation  $\{\Pi_h : h \in H\}$ .

The dotted curve represents the function  $h \mapsto \Psi(\Pi_h)$ . The blue line represents the tangent to the previous curve at h=0, which is indeed differentiable around h=0. It is derived by simple geometric arguments. In the next subsection, we formalize what it means to be smooth for the statistical mapping  $\Psi$ . Once the presentation is complete, we will be able to derive a closed-form expression for the slope of the blue curve from the chunk of code where draw\_from\_another\_experiment is defined.

**2.5** Being smooth, second pass. Let us now describe what it means for statistical mapping  $\Psi$  to be smooth at every  $P \in \mathcal{M}$ . The description necessitates the introduction of fluctuations.

For every direction\*  $s: \mathcal{O} \to \mathbb{R}$  such that  $s \neq 0^{\dagger}$ ,  $E_P(s(O)) = 0$  and s bounded by, say, M, for every  $h \in H \equiv ]-M^{-1}, M^{-1}[$ , we can define a law  $P_h \in \mathcal{M}$  by setting  $P_h \ll P^{\ddagger}$  and

$$\frac{dP_h}{dP}(O) \equiv 1 + hs(O),\tag{3}$$

<sup>\*</sup>A direction is a measurable function.

<sup>&</sup>lt;sup>†</sup>That is, s(O) is not equal to zero P-almost surely.

<sup>&</sup>lt;sup>‡</sup>That is,  $P_h$  is dominated by P: if an event A satisfies P(A) = 0, then necessarily  $P_h(A) = 0$  too.

that is,  $P_h$  has density (1 + hs) with respect to (w.r.t.) P. We call  $\{P_h : h \in H\}$  a fluctuation of P in direction s because

(i) 
$$P_h|_{h=0} = P$$
, (ii)  $\frac{d}{dh} \log \frac{dP_h}{dP}(O)\Big|_{h=0} = s(O)$ . (4)

The fluctuation is a one-dimensional parametric submodel of  $\mathcal{M}$ .

Statistical mapping  $\Psi$  is smooth at every  $P \in \mathcal{M}$  because, for each  $P \in \mathcal{M}$ , there exists a so called efficient influence curve  $P \in \mathcal{M}$  such that  $E_P(D^*(P)(O)) = 0$  and, for any direction S as above, if  $P_h : h \in H$  is defined as in (3), then the real-valued mapping  $h \mapsto \Psi(P_h)$  is differentiable at h = 0, with a derivative equal to

$$E_P\left(D^*(P)(O)s(O)\right). \tag{5}$$

Interestingly, if a fluctuation  $\{P_h : h \in H\}$  satisfies (4) for a direction s such that  $s \neq 0$ ,  $E_P(s(O)) = 0$  and  $\operatorname{Var}_P(s(O)) < \infty$ , then  $h \mapsto \Psi(P_h)$  is still differentiable at h = 0 with a derivative equal to (5) (beyond fluctuations of the form (3)).

The influence curves  $D^*(P)$  convey valuable information about  $\Psi$ . For instance, an important result from the theory of inference based on semiparametric models guarantees that if  $\psi_n$  is a regular  $\P$  estimator of  $\Psi(P)$  built from n independent observations drawn from P, then the asymptotic variance of the centered and rescaled  $\sqrt{n}(\psi_n - \Psi(P))$  cannot be smaller than the variance of the P-specific efficient influence curve, that is,

$$Var_P(D^*(P)(O)). (6)$$

In this light, an estimator  $\psi_n$  of  $\Psi(P)$  is said asymptotically efficient at P if it is regular at P and such that  $\sqrt{n}(\psi_n - \Psi(P))$  converges in law to the centered Gaussian law with variance (6), which is called the Cramér-Rao bound.

**2.6** The efficient influence curve. It is not difficult to check (do we give the proof?) that the efficient influence curve  $D^*(P)$  of  $\Psi$  at  $P \in \mathcal{M}$  writes as  $D^*(P) \equiv D_1^*(P) + D_2^*(P)$  where  $D_1^*(P)$  and  $D_2^*(P)$  are given by

$$D_1^*(P)(O) \equiv \bar{Q}(1, W) - \bar{Q}(0, W) - \Psi(P),$$
  
$$D_2^*(P)(O) \equiv \frac{2A - 1}{\ell \bar{G}(A, W)} (Y - \bar{Q}(A, W)),$$

<sup>§</sup>It is a measurable function.

<sup>¶</sup>We can view  $\psi_n$  as the by product of an algorithm  $\widehat{\Psi}$  trained on independent observations  $O_1, \ldots, O_n$  drawn from P. The estimator is regular at P (w.r.t. the maximal tangent space) if, for any direction  $s \neq 0$  such that  $E_P(s(O)) = 0$  and  $\operatorname{Var}_P(s(O)) < \infty$  and fluctuation  $\{P_h : h \in H\}$  satisfying (4), the estimator  $\psi_{n,1/\sqrt{n}}$  of  $\Psi(P_{1/\sqrt{n}})$  obtained by training  $\widehat{\Psi}$  on independent observations  $O_1, \ldots, O_n$  drawn from  $P_{1/\sqrt{n}}$  is such that  $\sqrt{n}(\psi_{n,1/\sqrt{n}} - \Psi(P_{1/\sqrt{n}}))$  converges in law to a limit that does not depend on s.

with shorthand notation  $\ell \bar{G}(A, W) \equiv A\bar{G}(W) + (1 - A)(1 - \bar{G}(W))$ . The following chunk of code enables the computation of the values of the efficient influence curve  $D^*(P)$  at observations drawn from P (note that it is necessary to provide the value of  $\Psi(P)$ , or a numerical approximation thereof, through argument psi).

```
eic <- function(obs, psi) {
    Qbar <- attr(obs, "Qbar")
    Gbar <- attr(obs, "Gbar")
    QAW <- Qbar(obs[, c("A", "W")])
    gW <- Gbar(obs[, "W"])
    lgAW <- obs[, "A"] * gW + (1 - obs[, "A"]) * (1 - gW)
    ( Qbar(cbind(1, obs[, "W"])) - Qbar(cbind(0, obs[, "W"])) - psi ) +
        (2 * obs[, "A"] - 1) / lgAW * (obs[, "Y"] - QAW)
}

(eic(five_obs, psi = psi_hat))</pre>
```

```
## [1] -1.0729162  0.1645268  0.2829249 -0.5969299 -0.4555560
(eic(five_obs_from_another_experiment, psi = psi_Pi_zero))
```

```
## [1] -0.15461023 -0.11720740 0.05266769 -0.09541458 -0.19365206
```

**2.7** Computing and comparing Cramér-Rao bounds. We can use eic to numerically approximate the Cramér-Rao bound at  $P_0$ :

```
obs <- draw_from_experiment(B)
(cramer_rao_hat <- var(eic(obs, psi = psi_hat)))</pre>
```

## [1] 0.2546553

and the Cramér-Rao bound at  $\Pi_0$ :

```
obs_from_another_experiment <- draw_from_another_experiment(B)
(cramer_rao_Pi_zero_hat <- var(eic(obs_from_another_experiment, psi = 59/300)))</pre>
```

## [1] 0.09512008

```
(ratio <- sqrt(cramer_rao_Pi_zero_hat/cramer_rao_hat))</pre>
```

## [1] 0.6111668

We thus discover that of the statistical parameters  $\Psi(P_0)$  and  $\Psi(\Pi_0)$ , the latter is easier to target than the former. Heuristically, for large sample sizes, the narrowest (efficient) confidence intervals for  $\Psi(\Pi_0)$  are approximately 0.61 (rounded to two decimal places) smaller than their counterparts for  $\Psi(P_0)$ .

**2.8** Revisiting Section 2.4. It is not difficult either (though a little cumbersome) (do we give the proof? I'd rather not) to verify that  $\{\Pi_h : h \in [-1,1]\}$  is a fluctuation of  $\Pi_0$  in the direction of  $\sigma_0$  (in the sense of (3)) given, up to a constant, by

$$\sigma_0(O) \equiv -10\sqrt{W}A \times \beta_0(A, W) \left( \log(1 - Y) + \sum_{k=0}^3 (k + \beta_0(A, W))^{-1} \right) + \text{constant},$$

where 
$$\beta_0(A, W) \equiv \frac{1 - \bar{Q}_{\Pi_0}(A, W)}{\bar{Q}_{\Pi_0}(A, W)}$$
.

Consequently, the slope of the dotted curve in Figure 1 is equal to

$$E_{\Pi_0}(D^*(\Pi_0)(O)\sigma_0(O)) \tag{7}$$

(since  $D^*(\Pi_0)$  is centered under  $\Pi_0$ , knowing  $\sigma_0$  up to a constant is not problematic).

Let us check this numerically. In the next chunk of code, we implement direction  $\sigma_0$  with sigmaO\_draw\_from\_another\_experiment, then we numerically approximate (7) (pointwise and with a confidence interval of asymptotic level 95%):

```
sigma0_draw_from_another_experiment <- function(obs) {</pre>
  ## preliminary
  Qbar <- attr(obs, "Qbar")</pre>
  QAW <- Qbar(obs[, c("A", "W")])
  shape1 <- Arguments$getInteger(attr(obs, "shape1"), c(1, Inf))</pre>
  ## computations
  betaAW <- shape1 * (1 - QAW) / QAW
  out <- log(1 - obs[, "Y"])
  for (int in 1:shape1) {
    out <- out + 1/(int - 1 + betaAW)
  }
  out <- - out * shape1 * (1 - QAW) / QAW * 10 * sqrt(obs[, "W"]) * obs[, "A"]
  ## no need to center given how we will use it
  return(out)
}
vars <- eic(obs_from_another_experiment, psi = 59/300) *</pre>
  sigma0 draw from another experiment(obs from another experiment)
sd hat <- sd(vars)
(slope_hat <- mean(vars))</pre>
```

```
## [1] 1.35969
(slope_CI <- slope_hat + c(-1, 1) * qnorm(1 - alpha / 2) * sd_hat / sqrt(B))</pre>
```

## [1] 1.354437 1.364944

Equal to 1.349 (rounded to three decimal places), the first numerical approximation slope\_approx is not too off.

**2.9 Double-robustness** The efficient influence curve  $D^*(P)$  at  $P \in \mathcal{M}$  enjoys another remarkable property: it is double-robust. Specifically, if we define for all  $P' \in \mathcal{M}$ 

$$\operatorname{Rem}_{P}(\bar{Q}', \bar{G}') \equiv \Psi(P') - \Psi(P) + E_{P}(D^{*}(P')(O)), \tag{8}$$

then the so called remainder term  $\operatorname{Rem}_{P}(\bar{Q}', \bar{G}')$  satisfies

For any (measurable)  $f: \mathcal{O} \to \mathbb{R}$ , we denote  $||f||_P = E_P(f(\mathcal{O})^2)^{1/2}$ .

$$\operatorname{Rem}_{P}(\bar{Q}', \bar{G}')^{2} \leq \|\bar{Q}' - \bar{Q}\|_{P}^{2} \times \|(\bar{G}' - \bar{G})/\ell\bar{G}'\|_{P}^{2}. \tag{9}$$

In particular, if

$$E_P(D^*(P')(O)) = 0,$$
 (10)

and either  $\bar{Q}' = \bar{Q}$  or  $\bar{G}' = \bar{G}$ , then  $\operatorname{Rem}_P(\bar{Q}', \bar{G}') = 0$  hence  $\Psi(P') = \Psi(P)$ . In words, if P' solves the so called P-specific efficient influence curve equation (10) and if, in addition, P' has the same  $\bar{Q}$ -component or  $\bar{G}$ -component as P, then  $\Psi(P') = \Psi(P)$  no matter how P' may differ from P otherwise. This property is useful to build consistent estimators of  $\Psi(P)$ .

However, there is much more to double-robustness than the above straightforward implication. Indeed, 8 is useful to build a consistent etimator of  $\Psi(P)$  that, in addition, satisfies a central limit theorem and thus lends itself to the construction of confidence intervals.

Let  $P_n^0 \in \mathcal{M}$  be an element of model  $\mathcal{M}$  of which the choice is data-driven, based on observing n independent draws from P. Equality 8 reveals that the statistical behavior of the corresponding substitution estimator  $\psi_n^0 \equiv \Psi(P_n^0)$  is easier to analyze when the remainder term  $\operatorname{Rem}_P(\bar{Q}_n^0, \bar{G}_n^0)$  goes to zero at a fast (relative to n) enough rate. In light of 9, this happens if the features  $\bar{Q}_n^0$  and  $\bar{G}_n^0$  of  $P_n^0$  converge to their counterparts under P at rates of which the product is fast enough.

**2.10** Inference assuming  $\bar{G}_0$  known, or not, first pass. Let  $O_1, \ldots, O_n$  be a sample of independent observations drawn from  $P_0$ . Let  $P_n$  be the corresponding empirical measure, *i.e.*, the law consisting in drawing one among  $O_1, \ldots, O_n$  with equal probabilities  $n^{-1}$ .

Let us assume for a moment that we know  $\bar{G}_0$ . This may be the case indeed if  $P_0$  was a controlled experiment. Note that, on the contrary, assuming  $\bar{Q}_0$  known would be difficult to justify.

```
Gbar <- attr(obs, "Gbar")
iter <- 1e3</pre>
```

Then, the alternative expression

$$\psi_0 = E_{P_0} \left( \frac{2A - 1}{\ell \bar{G}_0(A, W)} Y \right) \tag{11}$$

suggests to estimate  $\psi_0$  with

$$\psi_n^b \equiv E_{P_n} \left( \frac{2A - 1}{\ell \bar{G}_0(A, W)} Y \right) = \frac{1}{n} \sum_{i=1}^n \left( \frac{2A_i - 1}{\ell \bar{G}_0(A_i, W_i)} Y_i \right). \tag{12}$$

Note how  $P_n$  is substituted for  $P_0$  in (12) relative to (11).

It is easy to check that  $\psi_n^b$  estimates  $\psi_0$  consistently, but this is too little to request from an estimator of  $\psi_0$ . Better,  $\psi_n^b$  also satisfies a central limit theorem:  $\sqrt{n}(\psi_n^b - \psi_0)$  converges in law to a centered Gaussian law with asymptotic variance

$$v^b \equiv \operatorname{Var}_{P_0} \left( \frac{2A-1}{\ell \bar{G}_0(A,W)} Y \right),$$

where  $v^b$  can be consistently estimated by its empirical counterpart

$$v_n^b \equiv \text{Var}_{P_n} \left( \frac{2A - 1}{\ell \bar{G}_0(A, W)} Y \right) = \frac{1}{n} \sum_{i=1}^n \left( \frac{2A_i - 1}{\ell \bar{G}_0(A_i, W_i)} Y_i - \psi_n^b \right)^2.$$
 (13)

Let us investigate how  $\psi_n^b$  behaves based on obs. Because we are interested in the law of  $\psi_n^b$ , the next chunk of code constitutes iter = 1000 independent samples of independent observations drawn from  $P_0$ , each consisting of n equal to row(obs)/iter = 1000 data points, and computes the realization of  $\psi_n^b$  on all samples.

Before proceeding, let us introduce

$$\psi_n^a \equiv E_{P_n} (Y|A=1) - E_{P_n} (Y|A=0)$$

$$= \frac{1}{n_1} \sum_{i=1}^n \mathbf{1} \{A_i = 1\} Y_i - \frac{1}{n_0} \sum_{i=1}^n \mathbf{1} \{A_i = 0\} Y_i$$

$$= \frac{1}{n_1} \sum_{i=1}^n A_i Y_i - \frac{1}{n_0} \sum_{i=1}^n (1 - A_i) Y_i,$$

where  $n_1 = \sum_{i=1}^n A_i = n - n_0$  is the number of observations  $O_i$  such that  $A_i = 1$ . It is an estimator of

$$E_{P_0}(Y|A=1) - E_{P_0}(Y|A=0).$$

We seize this opportunity to demonstrate numerically the obvious fact that  $\psi_n^a$  does not estimate  $\psi_0$ .

```
## # A tibble: 2 x 2
## type bias
```

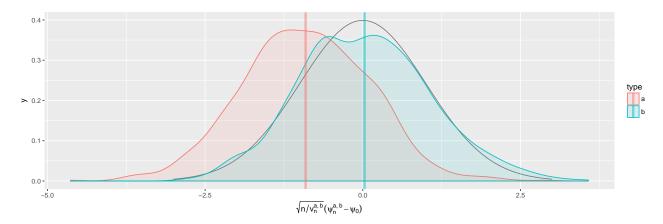

Figure 2: Kernel density estimators of the law of two estimators of  $\psi_0$  (recentered and renormalized), one of them misconceived (a), the other assuming that  $\bar{G}_0$  is known (b). Built based on iter independent realizations of each estimator.

```
##
     <chr>>
             <dbl>
## 1 a
           -0.907
## 2 b
            0.0269
debug(ggplot2::stat_density)
fig <- ggplot() +
  geom_line(aes(x = x, y = y),
            data = tibble(x = seq(-3, 3, length.out = 1e3),
                          y = dnorm(x)),
            linetype = 1, alpha = 0.5) +
  geom_density(aes(clt, fill = type, colour = type),
               psi_hat_ab, alpha = 0.1) +
  geom_vline(aes(xintercept = bias, colour = type),
             bias_ab, size = 1.5, alpha = 0.5)
fig +
  labs(x = expression(paste(sqrt(n/v[n]^{list(a, b)})*(psi[n]^{list(a, b)} - psi[0]))))
```

Let  $v_n^a$  be n times the empirical variance of the iter realizations of  $\psi_n^a$ . By the above chunk of code, the averages of  $\sqrt{n/v_n^a}(\psi_n^a-\psi_0)$  and  $\sqrt{n/v_n^b}(\psi_n^b-\psi_0)$  computed across the realizations of the two estimators are respectively equal to -0.907 and 0.027 (both rounded to three decimal places — see bias\_ab). Interpreted as amounts of bias, those two quantities are represented by vertical lines in Figure 2. The red and blue bell-shaped curves represent the empirical laws of  $\psi_n^a$  and  $\psi_n^b$  (recentered and renormalized) as estimated by kernel density estimation. The latter is close to the black curve, which represents the standard normal density.

**2.11 Inference assuming**  $\bar{G}_0$  known, or not, second pass. At the beginning of Section 2.10, we assumed that  $\bar{G}_0$  was known. Let us suppose now that it is not. The definition of  $\psi_n^b$  can be adapted to overcome this difficulty, by substituting an estimator of  $\ell\bar{G}_0$  for  $\ell\bar{G}_0$  in (12).

For simplicity, we consider the case that  $\bar{G}_0$  is estimated by minimizing a loss function on a single working model, both fine-tune-parameter-free. By adopting this stance, we exclude estimating procedures that involve penalization (e.g. the LASSO) or aggregation of competing estimators (via stacking/super learning) – see Section 2.12. Defined in the next chunk of code, the generic function estimate\_G fits a user-specified working model by minimizing the empirical risk associated to the user-specified loss function and provided data, and

the generic function predict\_lGAW (merely a convenient wrapper) estimates  $\ell \bar{G}_0(A, W)$  for any (A, W) based on the output of estimate\_G.

```
estimate_G <- function(dat, algorithm, ...) {</pre>
  if (!attr(algorithm, "ML")) {
    fit <- algorithm[[1]](formula = algorithm[[2]], data = dat)</pre>
    Ghat <- function(newdata) {</pre>
      predict(fit, newdata, type = "response")
    }
  } else {
    fit <- algorithm(dat, ...)</pre>
    Qhat <- function(newdata) {</pre>
      caret::predict.train(fit, newdata)
    }
  }
  return(Ghat)
}
predict_lGAW <- function(A, W, algorithm, threshold = 0.05, ...) {</pre>
  ## a wrapper to use in a call to 'mutate'
  ## (a) fit the working model
  dat \leftarrow data.frame(A = A, W = W)
  Ghat <- estimate_G(dat, algorithm, ...)</pre>
  ## (b) make predictions based on the fit
  Ghat_W <- Ghat(dat)</pre>
  1GAW \leftarrow A * Ghat_W + (1 - A) * (1 - Ghat_W)
  pmin(1 - threshold, pmax(lGAW, threshold))
}
```

## Comment on new structure of estimate\_G.

Note how the prediction of any  $\ell \bar{G}_0(A, W)$  is manually bounded away from 0 and 1 at the last line of predict\_lGAW. This is desirable because the *inverse* of each  $\ell \bar{G}_0(A_i, W_i)$  appears in the definition of  $\psi_n^b$  (12).

For sake of illustration, we choose argument working\_model\_G\_one of function estimate\_G as follows:

```
## A ~ I(W^0.5) + I(W^1) + I(W^1.5) + I(W^2)
```

In words, we choose the so called logistic (or negative binomial) loss function  $L_a$  given by

$$-L_a(f)(A, W) \equiv A \log f(W) + (1 - A) \log(1 - f(W)) \tag{14}$$

for any function  $f:[0,1] \to [0,1]$  paired with the working model  $\mathcal{F} \equiv \{f_{\theta}: \theta \in \mathbb{R}^5\}$  where, for any  $\theta \in \mathbb{R}^5$ ,

logit  $f_{\theta}(W) \equiv \theta_0 + \sum_{j=1}^4 \theta_j W^{j/2}$ . The working model is well specified: it happens that  $\bar{G}_0$  is the unique minimizer of the risk entailed by  $L_a$  over  $\mathcal{F}$ :

$$\bar{G}_0 = \operatorname*{arg\,min}_{f_\theta \in \mathcal{F}} E_{P_0} \left( L_a(f_\theta)(A, W) \right).$$

Therefore, the estimator  $\bar{G}_n$  output by estimate\_G and obtained by minimizing the empirical risk

$$E_{P_n}(L_a(f_\theta)(A, W)) = \frac{1}{n} \sum_{i=1}^n L_a(f_\theta)(A_i, W_i)$$

over  $\mathcal{F}$  consistently estimates  $\bar{G}_0$ .

In light of (12), introduce

$$\psi_n^c = \frac{1}{n} \sum_{i=1}^n \left( \frac{2A_i - 1}{\ell \bar{G}_n(A_i, W_i)} Y_i \right). \tag{15}$$

Because  $\bar{G}_n$  minimizes the empirical risk over a finite-dimensional and well-specified working model,  $\sqrt{n}(\psi_n^c - \psi_0)$  converges in law to a centered Gaussian law. Let us compute  $\psi_n^c$  on the same iter = 1000 independent samples of independent observations drawn from  $P_0$  as in Section 2.10:

```
## # A tibble: 3 x 2
## type bias
## <chr> <dbl>
## 1 a   -0.907
## 2 b     0.0269
## 3 c   -0.0870
```

Note how we exploit the independent realizations of  $\psi_n^c$  to estimate the asymptotic variance of the estimator with  $v_n^c/n$ . By the above chunk of code, the average of  $\sqrt{n/v_n^c}(\psi_n^c-\psi_0)$  computed across the realizations is equal to -0.087 (rounded to three decimal places — see bias\_abc). We represent the empirical laws of the recentered and renormalized  $\psi_n^a$ ,  $\psi_n^b$  and  $\psi_n^c$  in Figures 3 (kernel density estimators) and 4 (quantile-quantile plots).

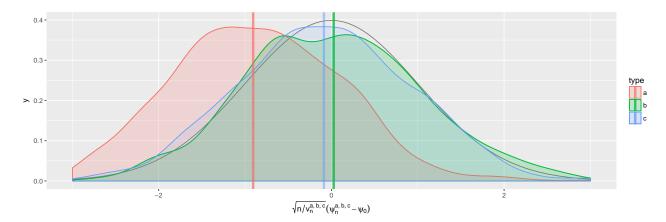

Figure 3: Kernel density estimators of the law of three estimators of  $\psi_0$  (recentered and renormalized), one of them misconceived (a), one assuming that  $\bar{G}_0$  is known (b) and one that hinges on the estimation of  $\bar{G}_0$  (c). The present figure includes Figure 2 (but the colors differ). Built based on iter independent realizations of each estimator.

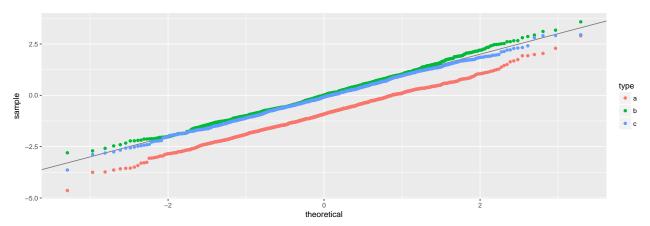

Figure 4: Quantile-quantile plot of the standard normal law against the empirical laws of three estimators of  $\psi_0$ , one of them misconceived (a), one assuming that  $\bar{G}_0$  is known (b) and one that hinges on the estimation of  $\bar{G}_0$  (c). Built based on iter independent realizations of each estimator.

Figures 3 and 4 reveal that  $\psi_n^c$  behaves as well as  $\psi_n^b$  — but remember that we did not discuss how to estimate its asymptotic variance.

- 2.12 Exercises. The questions are asked in the context of Sections 2.10 and 2.11.
  - 1. Building upon the piece of code devoted to the repeated computation of  $\psi_n^b$  and its companion quantities, construct confidence intervals for  $\psi_0$  of (asymptotic) level 95%, and check if the empirical coverage is satisfactory. Note that if the coverage was exactly 95%, then the number of confidence intervals that would contain  $\psi_0$  would follow a binomial law with parameters iter and 0.95, and recall that function binom.test performs an exact test of a simple null hypothesis about the probability of success in a Bernoulli experiment against its three one-sided and two-sided alternatives.
  - 2. The wrapper predict\_lGAW makes predictions by fitting a working model on the same data points as those for which predictions are sought. Why could that be problematic? Can you think of a simple workaround, implement and test it?
  - 3. Discuss what happens when the dimension of the (still well-specified) working model grows. You could use the following chunk of code

play around with argument powers (making sure that 1/2 and 1 belong to it), and plot graphics similar to those presented in Figures 3 and 4.

4. Discuss what happens when the working model is mis-specified. You could use the following chunk of code:

```
## A ~ I(cos(W)) + I(sin(W)) + I(sqrt(W)) + I(log(W)) + I(exp(W))
```

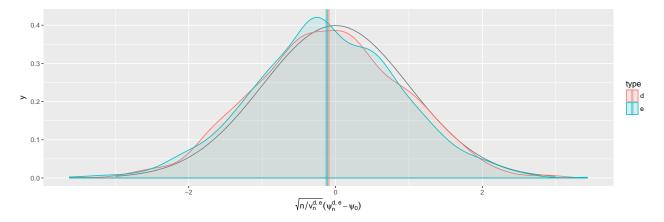

5. Prawing inspiration from (13), one may consider estimating the asymptotic variance of  $\psi_n^c$  with the counterpart of  $v_n^b$  obtained by substituting  $\ell \bar{G}_n$  for  $\ell \bar{G}_0$  in (13). By adapting the piece of code devoted to the repeated computation of  $\psi_n^b$  and its companion quantities, discuss if that would be legitimate.

```
